

Software requirements for caTools

1 Introduction

caTools represent a set of tools used to read, write and display information about EPICS channels. Two sets of tools currently exist. First set is written in TCL programming language and have been in use at PSI for many years. Later a second, set of tools was added to EPICS base. The basic functionalities of both are equal, but each has different additional features. Furthermore, the input and output of both tools is not compatible.

The new version of the TCL programming language is not compatible to the previous ones, so the existing PSI tools cannot be used with the new TCL version. Thus a new set of caTools is needed, that will be backwards compatible with the existing PSI tools and that will have additional features from EPICS base tool set added.

An analysis of the current tools is available inside a Jira ticket [1]. A preliminary list of command line arguments for the new tools is available inside a Jira ticket [2] as `arguments.pdf` attachment. The rest of this document describes the requirements for the new set of caTools.

2 Requirements

2.1 General

2.1.1. The default output format will be in the following form:

```
[date] [time] [channel name] [value] [EGU] [severity and status]
```

2.1.2. The following tools shall be available:

caget Reads and formats a value from each channel specified by the user. This tool shall honor the default output format.

cagets Writes 1 to PROC field of a channel and reads it back after channel has finished processing. This tool shall honor the default output format.

caput Writes a value to a channel and reads it back. This tool shall honor the default output format.

caputq Writes a value to a channel, but does not wait for the processing to finish. Does not have any output (except if an error occurs).

cainfo Displays detailed information about a channel. Has a custom output.

camon Monitors a set of channels and outputs their values on each change. This tool shall honor the default output format.

cado Writes 1 to a channel, but does not wait for the processing to finish. Does not have any output (except if an error occurs).

cawait Monitors a channel and waits until specified conditions for the channel match. Then the value is displayed. This tool shall honor the default output format.

2.1.3. caTools shall be written in C programming language.

2.1.4. caTools shall compile on the following platforms:

- SL6-x86 SL6-x86_64,
- eldk52-e500v2,
- eldk42-ppc4xxFP.

2.1.5. Input and expected output shall be backwards compatible with existing PSI tools, except for **caInfo** tool and array handling.

2.1.6. The user shall be able to request specified compound data type (eg. DBR_TIME_CHAR).

2.1.7. The user shall be able to select channel access timeout (eg. how long to wait for channel to connect).

2.1.8. Date and time of the record execution shall be available (CA server date/time).

2.1.9. Date and time of the record printout shall be available (client local date/time).

2.2 Tool specifics

2.2.1. **camon** shall have options to select incremental time-stamp:

- Time elapsed since start of program.
- Time elapsed since last update.
- Time elapsed since last update, by channel.

2.2.2. **camon** shall have an option to exit monitoring after user specified number of updates.

2.2.3. **cawait** shall have an option to exit after a user specified timeout.

2.2.4. **caInfo** tool shall display all the information available in `DBR_CTRL_XXX` compound data type.

2.3 Value formatting

2.3.1. The format of the **decimal** values shall be settable:

- Round the value to closest integer, round to next integer, round to previous integer.
- Scientific notation (mantissa/exponent) with specified precision - %e format.
- Decimal floating point notation with specified precision - %f format.
- Use the shortest representation between %e and %f.
- Override the PREC field defined in the record.

2.3.2. The user shall be able to set the format of the **integer** values to hex, binary or octal.

2.3.3. The user shall be able to force interpretation of **enum** and **char** values as integers or characters / array of characters.

2.4 Array handling

2.4.1. Arrays shall be printed as a list of values, where the formatting shall be based on the value type (eg. char type is displayed as an ASCII character, double type is displayed as a decimal number).

2.4.2. Array values separator shall be configurable.

- 2.4.3. The user shall be able to set the requested amount of array elements to read or write.

2.5 Output formatting

- 2.5.1. Severity and status shall be displayed when not in `NO_ALARM` state.
- 2.5.2. The user shall be able for force the severity and status to always be displayed.
- 2.5.3. The user shall be able for force the severity and status to never be displayed.
- 2.5.4. The user shall be able to hide channel name from the output.
- 2.5.5. The user shall be able to hide engineering units (EGU) from displaying next to values.
- 2.5.6. The value and output formatting shall be applied to all tools that honor the default output format equally.
